An Introduction To Time Waveform Introduction. The analysis of time waveform data is not a new technique. In the early days of vibration analysis time waveform data was viewed on oscilloscopes and frequency components calculated by hand. The relationship between frequency and time is as follows:  $f = 1/pAn$

 Instantaneous voltage is the voltage between two points at a particular moment in time. The voltage of a waveform at a given instant in time is called “Instantaneous voltage”. In the above diagram  $v_1, v_2, v_3, v_4, v_5, v_6, \dots$  are the instantaneous voltages of the sine wave.

 From Fourier we know that periodic waveforms can be modeled as the sum of harmonically-related sine waves. The Fourier Transform aims to decompose a cycle of an arbitrary waveform into its sine components; the Inverse Fourier Transform goes the other way—it converts a series of sine components into the resulting waveform.

ANALYSIS. If either an RC or RL circuit has a time constant 10 times greater than the duration of the input pulse, the circuits are capable of integration. Let's compute and graph the actual waveform that would result from a long time constant (10 times the pulse duration), a short time constant (1/10 of the pulse duration), and a medium time constant (that time constant ...)

 Light is a longitudinal wave that is able to pass through the vacuum jar, but sound is a transverse wave that has to move perpendicular to air. Light does not need a medium to travel through, but since sound waves must have a medium to vibrate, sound is not created where no air is present.
