objective $E(x)$ is a nonlinear least squares expression defined in terms of the photometric residual vector $r(x)$ $E(x) = \frac{1}{2} \|r(x)\|^2$. (7) The updates of the parameters to be optimized, x , follow a standard iterative optimization scheme, i.e. $x_{i+1} = x_i + \Delta x_i$.

Learning to Solve Nonlinear Least Squares for Monocular Stereo

Non-linear least squares is the form of least squares analysis used to fit a set of m observations with a model that is non-linear in n unknown parameters. It is used in some forms of nonlinear regression. The basis of the method is to approximate the model by a linear one and to refine the parameters by successive iterations. There are many similarities to linear least squares, but also some significant differences. In economic theory, the non-linear least squares method is applied in the probit.

Abstract: The use of an adaptive non-linear least squares algorithm to solve the inverse kinematic problem for robotic manipulators is proposed. The algorithm uses the Gauss-Newton model of the direct kinematic function with the Levenberg-Marquardt iteration.

Adaptive non-linear least squares for inverse kinematics ... In mathematics, and in particular linear algebra, the Moore–Penrose inverse $+$ of a matrix is the most widely known generalization of the inverse matrix. It was independently described by E. H. Moore in 1920, Arne Bjerhammar in 1951, and Roger Penrose in 1955. Earlier, Erik Ivar Fredholm had introduced the concept of a pseudoinverse of integral operators in 1903.
