In this book, expert dermatologists review state of the art knowledge concerning the clinical presentation and management of cutaneous diseases that develop in immunosuppressed individuals. A major aim is to enable dermatologists to identify the specific immunosuppressant responsible for a specific

adverse effect in patients receiving a complex medication regimen in the setting of transplantation. Further, the book will help the dermatologist to distinguish the cutaneous adverse effects of antiviral agents from effects arising directly from advancing HIV disease. Recognition of the cutaneous manifestations of often less common primary immunodeficiencies will also be emphasized. A final goal is to improve patient outcomes by identifying treatment strategies for skin disease arising in the immunosuppressed state. This book will be invaluable for a broad audience, from practicing dermatologists to medical and dermatology residents.

Throughout the biological world, bacteria thrive predominantly in surface-attached, matrix-enclosed, multicellular communities or biofilms, as opposed to isolated planktonic cells. This choice of lifestyle is not trivial, as it involves major shifts in the use of genetic information and cellular energy, and has profound consequences for bacterial physiology and survival. Growth within a biofilm can thwart immune function and antibiotic therapy and thereby complicate the treatment of infectious diseases, especially chronic and foreign device-associated infections. Modern studies of many important biofilms have advanced well beyond the descriptive stage, and have begun to provide molecular details of the structural, biochemical, and genetic processes that drive biofilm formation and its dispersion. There is much diversity in the details of biofilm development among various species, but there are also commonalities. In most species, environmental and nutritional conditions greatly influence biofilm development. Similar kinds of adhesive molecules often promote biofilm formation in diverse species. Signaling and regulatory processes that drive biofilm development are often conserved, especially among related bacteria. Knowledge of such processes holds great promise for efforts to control biofilm growth and combat biofilm-associated infections. This volume focuses on the biology of biofilms that affect human disease, although it is by no means comprehensive. It opens with chapters that provide the reader with current perspectives on biofilm development, physiology, environmental,

and regulatory effects, the role of quorum sensing, and resistance/phenotypic persistence to antimicrobial agents during biofilm growth.

Covering both common and uncommon conditions this book highlights an authentic evidence-based approach for the management of skin disorders. It presents the disorders in an alphabetical order and discusses their clinical features followed by a quick exposition of the relevant aetiology and pathogenesis. It then explains clinical diagnosis with the help of photographs vividly illustrating the features of the disorder. Management of the disorder has then been lucidly explained by organising the therapeutic data into a three-layered evidence-based approach. A large number of flowcharts summarising this approach have been included to serve as quick reference points for the busy clinician.

Lyme disease is spreading rapidly around the globe as ticks move into places they could not survive before. Mary Beth Pfeiffer argues it is the first epidemic to emerge in the era of climate change, infecting millions around the globe. She tells the heart-rending stories of its victims, families whose lives have been destroyed by a single, often unseen, tick bite. Pfeiffer also warns of the emergence of other tick-borne illnesses that make Lyme more difficult to treat and pose their own grave risks. Lyme is an impeccably researched account of an enigmatic disease, making a powerful case for action to fight ticks, heal patients, and recognize humanity's role in a modern scourge.
