A GIS Based Approach to the Spatial Analysis of the Fincastle Bison Kill Site (DIOx-5). LAP Lambert Academic Publishing
Khulna, the third largest metropolis of Bangladesh has been identified as one of the 15 most vulnerable coastal cities under climate change and it is believed that this scenario will be exacerbated with time by cyclone, saline water intrusion, submerging low-lying areas, and tidal and urban floods, etc. The city accommodates around 1.3 million people. The poorly drained city is approximately 2.5m above mean sea level. Climate change effect, especially sea level rise and flooding which is a major concern for the development of the city, was not considered when the structure plan 2000-2020 was prepared. First objective of the research is to analyze the land use policies under Structure Plan and second is to assess potential flood damage using secondary data namely Digital Elevation Model of Flood for 2020 and stage-damage functions for different major land uses with Geographic Information System grid-based approach. This research would provide a better understating of the future flood risk and facilitate the decision makers to review the existing and proposed land uses for taking mitigation and prevention measures.

ABSTRACT: A GIS-based study was undertaken comparing wetland coverages in 1926 and 1999 in selected sub-basins within Pinellas County, Florida, one of the most highly urbanized counties in south-central Florida with almost 50% of the existing land area developed into industrial, commercial or residential land uses (Pinellas County Planning Department, 2002). Wetlands were digitized from rectified 1926 aeriels and classified according to the FLUCCS classification system. Wetland coverage for the 1999 data set was extracted from FLUCCS 1999 land use coverage provided by the SWFWMD, and topology for both the 1926 and 1999 wetland and surface waters were created. Statistical and spatial analysis was then performed on the vector feature class layers to determine net wetland loss and gain, by watershed, within the sub-basin study area. Results indicate that substantial and statistically significant net losses in areal extent occurred between the 1926 and 1999 study time frames in most sub-basins for freshwater forested, freshwater herbaceous, saltwater herbaceous, non-vegetated wetlands and in total wetland areal extent. Both open water and upland exhibited statistically significant net increases in areal extent over the same time period. Losses are directly attributable to human-activity such as excavation, ditching, draining, and filling.
Future distribution of malaria in Tanzania: a GIS-based approach World Health Organization
Obesity has become one of the major issues in the United States. Research done by Center for Disease Control and other organizations revealed the relationship between obesity and physical inactivity. This is a major concern to the planners today, as the built environment affects the walkability of a neighborhood

and influences the pedestrians choice of walking. In this thesis, an effort is made to identify the measures of walkability and incorporate them into a GIS based model that would help in determining the level of walkability in a neighborhood. The model is then tested on a neighborhood in St Louis named Central West End.

A GIS Based Approach to Measure Walkability of a Neighborhood

"This book examines interdisciplinary approaches to GIS and spatial optimization in private and public organizations"--

A Remote Sensing-GIS Based Approach for Assessment of Chinook Salmon Rearing Habitat in the Unuk River Floodplain

"Remote sensing offers an alternative method to managers in mapping and monitoring the habitat within large rivers. Large rivers are not accommodating for traditional (foot) fish habitat surveys due to their size and typically complex habitat. This study investigates the use of digital aerial photos and thermal infrared images acquired in spring 2003-2005 to map and quantify juvenile chinook salmon (*Oncorhynchus tshawytscha*) habitat in a 12-river km section of the Unuk River floodplain in Southeast Alaska. Images were processed and analyzed to produce a fluvial landscape classification (7 landcover classes with an overall classification accuracy of ~84%) using a combination of aerial and thermal images. Change detection of large woody debris (LWD) was also examined and revealed both quantitative and distributional changes during the 3 years. A GIS-based habitat suitability analysis was used to identify potential chinook salmon rearing habitats including: river channel edges, sloughs, braids, pools associated with LWD and primary river channels. Overall 77.82 hectares of potentially medium/high chinook rearing habitats were identified. Results from this study provide a

promising foundation towards mapping and monitoring salmon habitat in large river systems for purposes of protection, conservation and monitoring to ensure sustainable stocks of salmon"--Leaf iii.

A GIS Based Approach Using DEMs

Chronic respiratory diseases, such as asthma and chronic obstructive pulmonary disease, kill more than 4 million people every year, and affect hundreds of millions more. These diseases erode the health and well-being of the patients and have a negative impact on families and societies. This report raises awareness of the huge impact of chronic respiratory diseases worldwide, and highlights the risk factors as well as ways to prevent and treat these diseases.

Assessing Fire Risk Using a GIS-based Approach

"A GIS offers a means by which the data collected during the assessment of possible mining impacts can be stored and manipulated. A GIS that provides a central focus point for the storage, manipulation and retrieval of information generated by the investigation into the geomorphological impact of the ERA Jabiluka Mine has been developed. Implementing a flexible, GIS-centred approach to data management allows the data storage, manipulation and retrieval powers of GIS to be retained whilst maintaining access to the functionality contained within these other software packages. The GIS has also been linked to the DistFW hydrology model and SIBERIA landform evolution model, to provide a more spatial approach to assessing the impact of mining on the long-term landform evolution of a catchment."-- Executive summary.

A GIS-based Approach for Assessment of Biomass

Resources and Routing Using Travel Distance and Time

This thesis is framed as a contribution to the study of spatial organization at the scale of the individual settlement, specifically in the context of the castros of Northwest Iberia. I argue that new approaches to the description and analysis of organizational properties are needed to improve the current state of research on this topic. I propose a new methodology toward this end by applying concepts and methods from spatial statistics in a GIS environment. I demonstrate the potential of my proposition through a preliminary case study involving two castro sites from northwestern Portugal: Cividade de Terroso and Castro de Romariz. I conclude by discussing the implications of my work for the study of architecture and spatial organization in castro settlements, suggesting that there is much to be gained by further pursuit and expansion of this new methodological approach
