The next shell down is now the outermost shell, which is now full — meaning there is very little tendency to gain or lose more electrons. The ion's electron configuration is the same as the nearest noble gas — the ion is said to be isoelectronic with the nearest noble gas. Atoms "prefer" to have a filled outermost shell because this is more electronically stable.

The azimuthal quantum number is a quantum number for an atomic orbital that determines its orbital angular momentum and describes the shape of the orbital. The azimuthal quantum number is the second of a set of quantum numbers which describe the unique quantum state of an electron (the others being the principal quantum number, the magnetic quantum number, and the spin quantum number).

These quantum numbers describe the size, shape, and orientation in space of the orbitals on an atom. The principal quantum number (n) describes the size of the orbital. Orbitals for which $n = 2$ are larger than those for which $n = 1$, for example. Because they have opposite electrical charges, electrons are attracted to the nucleus of the atom. Quantum Numbers and Electron Configurations The principal quantum number also tells us how many different orbitals (wave functions) have a particular energy. For any energy level, the total number of orbitals is n^2 . For example, there are four different orbitals that have $n = 2$ (because $2^2 = 4$) and nine different orbitals that have $n = 3$ (because $3^2 = 9$).
