A digital phase-locked loop or phase lock loop is a control system that generates an output signal whose phase is related to the phase of an input signal. There are several different types; the simplest is an electronic circuit consisting of a variable frequency oscillator and a phase detector in a feedback loop. The oscillator generates a periodic signal, and the phase detector compares the phase of that signal with the phase of the input periodic signal, adjusting the oscillator to keep the phases

Phase-locked loop - Wikipedia
 In its most basic configuration, a phase-locked loop compares the phase of a reference signal (F_{REF}) to the phase of an adjustable feedback signal (F_{IN}) F_0 , as seen in Figure 1. In Figure 2 there is a negative feedback control loop operating in the frequency domain. When the comparison is in steady-state, and the output frequency and phase are matched to the incoming frequency and phase of the error detector, we say that the PLL is locked.

 The digital phase-locked loop is based on a Costas loop, which is widely used in communication systems. The basic Costas loop is used to lock the frequency of the local NCO to the 5.89 MHz reference signal. Then, the three harmonic components can be locked to the reference signal by adjusting the frequency tuning words of the NCOs. A digital phase-locked loop based LLRF system - ScienceDirect
